**Problem 14.2.2.** Let  $f_c: \mathbb{C} \to \mathbb{C}$ ,  $f_c(z) = z^2 + c$  for  $c \in \mathbb{C}$ . Recall that a period n point  $z_0$  is super attracting if  $(f^n)'(z_0) = 0$ .

- i. If  $z_0$  and  $z_1$  are the fixed points of  $f_c$ , show that  $f'(z_0) + f'(z_1) = 2$ . Deduce that there can be at most one attracting fixed point. Give an example to show that  $f_c$  may not have any attracting fixed points.
- ii. Show that if  $f_c$  has a super-attracting fixed point  $z_0$ , then  $z_0 = 0$  and c = 0.
- iii. Find the value of c such that  $f_c$  has a super-attracting 2-cycle and give the associated 2-cycle.
- iv. Why is it that z=0 is a point in the orbit of a cycle if and only if the cycle is super-attracting?
- v. If  $f_c$  has a super-attracting 3-cycle, show that c satisfies the equation

$$c^3 + 2c + c + 1 = 0$$

Solution. i. If  $z_0$  and  $z_1$  are fixed points of  $f_c$ , then they are the roots of the equation  $z^2 - z + c = 0$ . Note that the solutions to this equation are of the form

$$z_0 = \frac{1 + \sqrt{1 - 4c}}{2}, \quad z_1 = \frac{1 - \sqrt{1 - 4c}}{2}.$$
 (1)

Since  $f'_c(z) = 2z$ , we see from (1) that

$$f'_c(z_0) + f'_c(z_1) = 2(z_0 + z_1) = 2\left(\frac{1 + \sqrt{1 - 4c}}{2} + \frac{1 - \sqrt{1 - 4c}}{2}\right) = 2.$$

Suppose that  $z_0 = r_0 e^{i\theta_0}$  is an attracting fixed point and let  $z_1 = r_1 e^{i\theta_1}$ . Since  $z_0$  is attracting, we have that  $|f'_c(z_0)| = 2|z_0| \le 1$  which implies that  $r_0 \le 1/2$ . Note that by the relation  $f'_c(z_0) + f'_c(z_1) = 2$  we have that  $z_1 = 1 - z_0 = 1 - r_0 e^{i\theta_0}$ . Thus,

$$|z_1| = |1 - r_0 e^{i\theta_0}| \ge ||1| - |r_0 e^{i\theta_0}|| = |1 - r_0|.$$

If  $r_0 = 1/2$ , then  $z_1 = z_0$  and there is at most one fixed point, otherwise if  $r_0 < 1/2$ , then  $|z_1| \ge |1 - r_0| > 1/2$  which implies that  $|f'_c(z_1)| > 1$  or that  $z_1$  is repelling.

If c = 5/4, then we see that  $|f'_c(z_0)| = |f'_c(z_1)| = \sqrt{5}/2$  where  $\sqrt{5}/2 > 1$ . Thus,  $f_c$  may not have any attracting fixed points.

- ii. Suppose that  $z_0$  is a super attracting fixed point of  $f_c$ . Then  $|f'_c(z_0)| = 2|z_0| = 0$ . Since  $|z_0| = 0$  if and only  $z_0 = 0$ , we readily see that  $z_0 = 0$ . Note that  $z_0$  is of the form presented in (1). Thus,  $(1 \pm \sqrt{1-4c})/2 = 0$  which implies that 1 4c = 1 or that c = 0.
- iii. The 2-cycles of  $f_c$  are solutions of the equation  $f_c^2(z) z = 0$  that are also not solutions of  $f_c(z) z = z^2 z + c = 0$ . Factoring  $f_c^2(z) z$  we see that

$$f_c^2(z) - z = (z^2 - z + c)(z^2 + z + c + 1) = 0$$

if and only if z is a fixed point or if

$$z_2 = \frac{-1 - \sqrt{-3 - 4c}}{2}, \quad z_3 = \frac{-1 + \sqrt{-3 - 4c}}{2}.$$

Thus,  $\{z_2, z_3\}$  forms a 2-cycle of  $f_c$ . This 2-cycle will be super-attracting if and only if

$$\left| (f_c^2)'(z_2) \right| = \left| f_c'(z_2) f_c'(z_3) \right| = \left| \left( -1 - \sqrt{-3 - 4c} \right) \left( -1 + \sqrt{-3 - 4c} \right) \right| = 4|1 + c| = 0$$

Thus, the 2-cycle is super-attracting if and only if c = -1. Therefore, the super attracting 2-cycle is  $\{0, -1\}$ .

iv. For an *n*-cycle  $\{z_0, \ldots, z_{n-1}\}$  of  $f_c$  we see that

$$|(f_c^n)'(z_0)| = |f_c'(z_0) \cdots f_c'(z_{n-1})| = 2^n |z_0 \cdots z_{n-1}|.$$
(2)

Thus, from (2), we have that  $\{z_0, \ldots, z_{n-1}\}$  is a super-attracting *n*-cycle of  $f_c$  if and only if  $|(f_c^n)'(z_0)| = 0$  if and only if  $z_i = 0$  for some  $i = 0, \ldots, n-1$ .

v. Suppose that  $\{z_0, z_1, z_2\}$  is a super-attracting 3-cycle of  $f_c$ . Thus, we must have that

$$|f'_c(z_0)f'_c(z_1)f'_c(z_2)| = 2^3 |z_0z_1z_2| = 0$$

Without loss of generality, we may assume that  $z_0 = 0$ . Using the fact that  $f_c(z_0) = z_1 \neq z_0$  and  $f_c^2(z_0) = z_2 \neq z_0$ , we see that

$$z_1 = f_c(z_0) = z_0^2 + c = c$$
  
 $z_2 = f_c^2(z_0) = (z_0^2 + c)^2 + c = c^2 + c$ 

In order for this to be a 3-cycle, we require that  $f^3(z_0) = z_0 = 0$ , i.e. we require that

$$f_c^3(z_0) = f_c(f_c^2(z_0)) = (c^2 + c)^2 + c$$
$$= c^4 + 2c^3 + c^2 + c$$
$$= c(c^3 + 2c^2 + c + 1) = 0.$$

However, we must have that  $c \neq 0$  or  $z_0 = 0$  would not generate a 3-cycle. Therefore,  $\{z_0, z_1, z_2\}$  is a super-attracting 3-cycle if and only if  $c^3 + 2c^2 + c + 1 = 0$ .
